

Chapter 6

Programming in MATLAB

A computer program is a sequence of computer commands. In a simple program the commands are executed one after the other in the order they are typed. In this book, for example, all the programs that have been presented so far in script files are simple programs. Many situations, however, require more sophisticated programs in which commands are not necessarily executed in the order they are typed, or different commands (or groups of commands) are executed when the program runs with different input variables. For example, a computer program that calculates the cost of mailing a package uses different mathematical expressions to calculate the cost depending on the weight and size of the package, the content (books are less expensive to mail), and the type of service (airmail, ground, etc.). In other situations there might be a need to repeat a sequence of commands several times within a program. For example, programs that solve equations numerically repeat a sequence of calculations until the error in the answer is smaller than some measure.

MATLAB provides several tools that can be used to control the flow of a program. Conditional statements (Section 6.2) and the `switch` structure (Section 6.3) make it possible to skip commands or to execute specific groups of commands in different situations. `For` loops and `while` loops (Section 6.4) make it possible to repeat a sequence of commands several times.

It is obvious that changing the flow of a program requires some kind of decision-making process within the program. The computer must decide whether to execute the next command or to skip one or more commands and continue at a different line in the program. The program makes these decisions by comparing values of variables. This is done by using relational and logical operators, which are explained in Section 6.1.

It should also be noted that user-defined functions (introduced in Chapter 7) can be used in programming. A user-defined function can be used as a subprogram. When the main program reaches the command line that has the user-defined function, it provides input to the function and “waits” for the results. The user-

defined function carries out the calculations and transfers the results back to the main program, which then continues to the next command.

6.1 RELATIONAL AND LOGICAL OPERATORS

A relational operator compares two numbers by determining whether a comparison statement (e.g., $5 < 8$) is true or false. If the statement is true, it is assigned a value of 1. If the statement is false, it is assigned a value of 0. A logical operator examines true/false statements and produces a result that is true (1) or false (0) according to the specific operator. For example, the logical AND operator gives 1 only if both statements are true. Relational and logical operators can be used in mathematical expressions and, as will be shown in this chapter, are frequently used in combination with other commands, to make decisions that control the flow of a computer program.

Relational operators:

Relational operators in MATLAB are:

<u>Relational operator</u>	<u>Description</u>
<	Less than
>	Greater than
<=	Less than or equal to
>=	Greater than or equal to
==	Equal to
~=	Not Equal to

Note that the “equal to” relational operator consists of two = signs (with no space between them), since one = sign is the assignment operator. In other relational operators that consist of two characters there also is no space between the characters (<=, >=, ~=).

- Relational operators are used as arithmetic operators within a mathematical expression. The result can be used in other mathematical operations, in addressing arrays, and together with other MATLAB commands (e.g., `if`) to control the flow of a program.
- When two numbers are compared, the result is 1 (logical true) if the comparison, according to the relational operator, is true, and 0 (logical false) if the comparison is false.
- If two scalars are compared, the result is a scalar 1 or 0. If two arrays are compared (only arrays of the same size can be compared), the comparison is done *element-by-element*, and the result is a logical array of the same size with 1s and 0s according to the outcome of the comparison at each address.

- If a scalar is compared with an array, the scalar is compared with every element of the array, and the result is a logical array with 1s and 0s according to the outcome of the comparison of each element.

Some examples are:

```
>> 5>8
ans =
    0
```

Checks if 5 is larger than 8.
Since the comparison is false (5 is not larger than 8) the answer is 0.

```
>> a=5<10
a =
    1
```

Checks if 5 is smaller than 10, and assigns the answer to a.
Since the comparison is true (5 is smaller than 10) the number 1 is assigned to a.

```
>> y=(6<10)+(7>8)+(5*3==60/4)
```

Using relational operators in math expression.

Equal to 1 since 6 is smaller than 10.
Equal to 0 since 7 is not larger than 8.
Equal to 1 since 5*3 is equal to 60/4.

```
y =
    2
```

```
>> b=[15 6 9 4 11 7 14]; c=[8 20 9 2 19 7 10];
```

Define vectors b and c.

```
>> d=c>=b
d =
    0     1     1     0     1     1     0
```

Checks which c elements are larger than or equal to b elements.
Assigns 1 where an element of c is larger than or equal to an element of b.

```
>> b == c
ans =
    0     0     1     0     0     1     0
```

Checks which b elements are equal to c elements.

```
>> b~=c
ans =
    1     1     0     1     1     0     1
```

Checks which b elements are not equal to c elements.

```
>> f=b-c>0
f =
    1     0     0     1     0     0     1
```

Subtracts c from b and then checks which elements are larger than zero.

```
>> A=[2 9 4; -3 5 2; 6 7 -1]
```

Define a 3 × 3 matrix A.

```
A =
     2     9     4
    -3     5     2
     6     7    -1
```

Checks which elements in A are smaller than or equal to 2. Assigns the results to matrix B.

```
>> B=A<=2
```

```
B =
     1     0     0
     1     0     1
     0     0     1
```

- The results of a relational operation with vectors, which are vectors with 0s and 1s, are called logical vectors and can be used for addressing vectors. When a logical vector is used for addressing another vector, it extracts from that vector the elements in the positions where the logical vector has 1s. For example:

```
>> r = [8 12 9 4 23 19 10]
r =
     8     12     9     4    23    19    10
>> s=r<=10
s =
     1     0     1     1     0     0     1
>> t=r(s)
t =
     8     9     4    10
>> w=r(r<=10)
w =
     8     9     4    10
```

Define a vector r .

Checks which r elements are smaller than or equal to 10.

A logical vector s with 1s at positions where elements of r are smaller than or equal to 10.

Use s for addresses in vector r to create vector t .

Vector t consists of elements of r in positions where s has 1s.

The same procedure can be done in one step.

- Numerical vectors and arrays with the numbers 0s and 1s are not the same as logical vectors and arrays with 0s and 1s. Numerical vectors and arrays can not be used for addressing. Logical vectors and arrays, however, can be used in arithmetic operations. The first time a logical vector or an array is used in arithmetic operations it is changed to a numerical vector or array.
- Order of precedence: In a mathematical expression that includes relational and arithmetic operations, the arithmetic operations (+, −, *, /, \) have precedence over relational operations. The relational operators themselves have equal precedence and are evaluated from left to right. Parentheses can be used to alter the order of precedence. Examples are:

```
>> 3+4<16/2
ans =
     1
>> 3+(4<16)/2
ans =
    3.5000
```

+ and / are executed first.

The answer is 1 since $7 < 8$ is true.

$4 < 16$ is executed first, and is equal to 1, since it is true.

3.5 is obtained from $3 + 1/2$.

Logical operators:

Logical operators in MATLAB are:

<u>Logical operator</u>	<u>Name</u>	<u>Description</u>
& Example: A&B	AND	Operates on two operands (A and B). If both are true, the result is true (1); otherwise the result is false (0).
 Example: A B	OR	Operates on two operands (A and B). If either one, or both, are true, the result is true (1); otherwise (both are false) the result is false (0).
~ Example: ~A	NOT	Operates on one operand (A). Gives the opposite of the operand; true (1) if the operand is false, and false (0) if the operand is true.

- Logical operators have numbers as operands. A nonzero number is true, and a zero number is false.
- Logical operators (like relational operators) are used as arithmetic operators within a mathematical expression. The result can be used in other mathematical operations, in addressing arrays, and together with other MATLAB commands (e.g., `if`) to control the flow of a program.
- Logical operators (like relational operators) can be used with scalars and arrays.
- The logical operations AND and OR can have both operands as scalars, arrays, or one array and one scalar. If both are scalars, the result is a scalar 0 or 1. If both are arrays, they must be of the same size and the logical operation is done *element-by-element*. The result is an array of the same size with 1s and 0s according to the outcome of the operation at each position. If one operand is a scalar and the other is an array, the logical operation is done between the scalar and each of the elements in the array and the outcome is an array of the same size with 1s and 0s.
- The logical operation NOT has one operand. When it is used with a scalar the outcome is a scalar 0 or 1. When it is used with an array, the outcome is an array of the same size with 1s in positions where the array has nonzero numbers and 0s in positions where the array has 0s.

Following are some examples:

```
>> 3&7
```

```
3 AND 7.
```

```

ans =
    1
>> a=5|0
a =
    1
>> ~25
ans =
    0
>> t=25*((12&0)+(~0)+(0|5))
t =
    50
>> x=[9 3 0 11 0 15]; y=[2 0 13 -11 0 4];
>> x&y
ans =
    1    0    0    1    0    1
>> z=x|y
z =
    1    1    1    1    0    1
>> ~(x+y)
ans =
    0    0    0    1    1    0

```

3 and 7 are both true (nonzero), so the outcome is 1.

5 OR 0 (assign to variable a).

1 is assigned to a since at least one number is true (nonzero).

NOT 25.

The outcome is 0 since 25 is true (nonzero) and the opposite is false.

Using logical operators in a math expression.

Define two vectors x and y.

The outcome is a vector with 1 in every position where both x and y are true (nonzero elements), and 0s otherwise.

The outcome is a vector with 1 in every position where either or both x and y are true (nonzero elements), and 0s otherwise.

The outcome is a vector with 0 in every position where the vector x + y is true (nonzero elements), and 1 in every position where x + y is false (zero elements).

Order of precedence:

Arithmetic, relational, and logical operators can be combined in mathematical expressions. When an expression has such a combination, the result depends on the order in which the operations are carried out. The following is the order used by MATLAB:

<u>Precedence</u>	<u>Operation</u>
1 (highest)	Parentheses (if nested parentheses exist, inner ones have precedence)
2	Exponentiation
3	Logical NOT (~)
4	Multiplication, division
5	Addition, subtraction
6	Relational operators (>, <, >=, <=, ==, ~=)
7	Logical AND (&)
8 (lowest)	Logical OR ()

If two or more operations have the same precedence, the expression is executed in order from left to right.

It should be pointed out here that the order shown above is the one used since MATLAB 6. Previous versions of MATLAB used a slightly different order (& did not have precedence over |), so the user must be careful. Compatibility problems between different versions of MATLAB can be avoided by using parentheses even when they are not required.

The following are examples of expressions that include arithmetic, relational, and logical operators:

<pre>>> x=-2; y=5; >> -5<x<-1 ans = 0 >> -5<x & x<-1 ans = 1 >> ~(y<7) ans = 0 >> ~y<7 ans = 1 >> ~((y>=8) (x<-1)) ans = 0 >> ~(y>=8) (x<-1) ans = 1</pre>	<div style="border: 1px solid black; padding: 5px; margin-bottom: 10px;">Define variables x and y.</div> <div style="border: 1px solid black; padding: 5px; margin-bottom: 10px;">This inequality is correct mathematically. The answer, however, is false since MATLAB executes from left to right. $-5 < x$ is true ($=1$) and then $1 < -1$ is false (0).</div> <div style="border: 1px solid black; padding: 5px; margin-bottom: 10px;">The mathematically correct statement is obtained by using the logical operator &. The inequalities are executed first. Since both are true (1), the answer is 1.</div> <div style="border: 1px solid black; padding: 5px; margin-bottom: 10px;">$y < 7$ is executed first, it is true (1), and ~ 1 is 0.</div> <div style="border: 1px solid black; padding: 5px; margin-bottom: 10px;">$\sim y$ is executed first. y is true (1) (since y is nonzero), ~ 1 is 0, and $0 < 7$ is true (1).</div> <div style="border: 1px solid black; padding: 5px; margin-bottom: 10px;">$y \geq 8$ (false), and $x < -1$ (true) are executed first. OR is executed next (true). \sim is executed last, and gives false (0).</div> <div style="border: 1px solid black; padding: 5px;">$y \geq 8$ (false), and $x < -1$ (true) are executed first. NOT of $(y \geq 8)$ is executed next (true). OR is executed last, and gives true (1).</div>
--	---

Built-in logical functions:

MATLAB has built-in functions that are equivalent to the logical operators. These functions are:

and (A, B)	equivalent to $A \& B$
or (A, B)	equivalent to $A B$
not (A)	equivalent to $\sim A$

In addition, MATLAB has other logical built-in functions, some of which are described in the following table:

Function	Description	Example
<code>xor(a,b)</code>	Exclusive or. Returns true (1) if one operand is true and the other is false.	<pre>>> xor(7,0) ans = 1 >> xor(7,-5) ans = 0</pre>
<code>all(A)</code>	Returns 1 (true) if all elements in a vector A are true (nonzero). Returns 0 (false) if one or more elements are false (zero). If A is a matrix, treats columns of A as vectors, and returns a vector with 1s and 0s.	<pre>>> A=[6 2 15 9 7 11]; >> all(A) ans = 1 >> B=[6 2 15 9 0 11]; >> all(B) ans = 0</pre>
<code>any(A)</code>	Returns 1 (true) if any element in a vector A is true (nonzero). Returns 0 (false) if all elements are false (zero). If A is a matrix, treats columns of A as vectors, and returns a vector with 1s and 0s.	<pre>>> A=[6 0 15 0 0 11]; >> any(A) ans = 1 >> B = [0 0 0 0 0 0]; >> any(B) ans = 0</pre>
<code>find(A)</code> <code>find(A>d)</code>	<p>If A is a vector, returns the indices of the nonzero elements.</p> <p>If A is a vector, returns the address of the elements that are larger than d (any relational operator can be used).</p>	<pre>>> A=[0 9 4 3 7 0 0 1 8]; >> find(A) ans = 2 3 4 5 8 9 >> find(A>4) ans = 2 5 9</pre>

The operations of the four logical operators, `and`, `or`, `xor`, and `not` can be summarized in a truth table:

INPUT		OUTPUT				
A	B	AND A&B	OR A B	XOR (A,B)	NOT ~A	NOT ~B
false	false	false	false	false	true	true
false	true	false	true	true	true	false
true	false	false	true	true	false	true
true	true	true	true	false	false	false

Sample Problem 6-1: Analysis of temperature data

The following were the daily maximum temperatures (in °F) in Washington, DC, during the month of April 2002: 58 73 73 53 50 48 56 73 73 66 69 63 74 82 84 91 93 89 91 80 59 69 56 64 63 66 64 74 63 69 (data from the U.S. National Oceanic and Atmospheric Administration). Use relational and logical operations to determine the following:

- The number of days the temperature was above 75°.
- The number of days the temperature was between 65° and 80°.
- The days of the month when the temperature was between 50° and 60°.

Solution

In the script file below the temperatures are entered in a vector. Relational and logical expressions are then used to analyze the data.

```
T=[58 73 73 53 50 48 56 73 73 66 69 63 74 82 84 ...
    91 93 89 91 80 59 69 56 64 63 66 64 74 63 69];
```

Tabove75=T>=75; A vector with 1s at addresses where T >= 75.

NdaysTabove75=sum(Tabove75) Add all the 1s in the vector Tabove75.

Tbetween65and80=(T>=65) & (T<=80); A vector with 1s at addresses where T >= 65 and T <= 80.

NdaysTbetween65and80=sum(Tbetween65and80)
 Add all the 1s in the vector Tbetween65and80.

datesTbetween50and60=find((T>=50) & (T<=60))
 The function `find` returns the address of the elements in T that have values between 50 and 60.

The script file (saved as Exp6_1) is executed in the Command Window:

```
>> Exp6_1
NdaysTabove75 =          For 7 days the temp was above 75.
      7
NdaysTbetween65and80 =  For 12 days the temp was between 65 and 80.
      12
datesTbetween50and60 =          Dates of the month with
      1      4      5      7      21      23      temp between 50 and 60.
```

6.2 CONDITIONAL STATEMENTS

A conditional statement is a command that allows MATLAB to make a decision of whether to execute a group of commands that follow the conditional statement, or to skip these commands. In a conditional statement a conditional expression is stated. If the expression is true, a group of commands that follow the statement are executed. If the expression is false, the computer skips the group. The basic form of a conditional statement is:

`if` conditional expression consisting of relational and/or logical operators.

Examples:

```
if a < b
if c >= 5
if a == b
if a ~= 0
if (d<h) & (x>7)
if (x~=13) | (y<0)
```

All the variables must
have assigned values.

- Conditional statements can be a part of a program written in a script file or a user-defined function (Chapter 7).
- As shown below, for every `if` statement there is an `end` statement.

The `if` statement is commonly used in three structures, `if-end`, `if-else-end`, and `if-elseif-else-end`, which are described next.

6.2.1 The `if-end` Structure

The `if-end` conditional statement is shown schematically in Figure 6-1. The figure shows how the commands are typed in the program, and a flowchart that symbolically shows the flow, or the sequence, in which the commands are executed. As the program executes, it reaches the `if` statement. If the conditional expres-

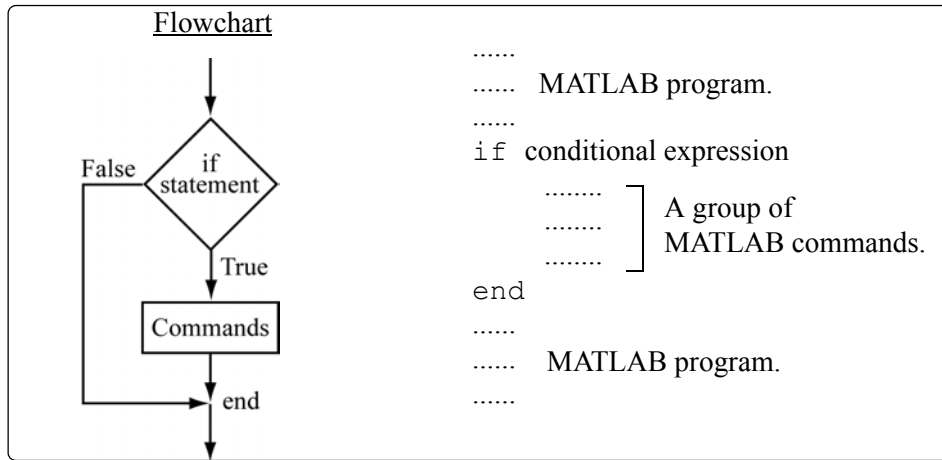

Figure 6-1: The structure of the `if`-`end` conditional statement.

sion in the `if` statement is true (1), the program continues to execute the commands that follow the `if` statement all the way down to the `end` statement. If the conditional expression is false (0), the program skips the group of commands between the `if` and the `end`, and continues with the commands that follow the `end`.

The words `if` and `end` appear on the screen in blue, and the commands between the `if` statement and the `end` statement are automatically indented (they don't have to be), which makes the program easier to read. An example where the `if`-`end` statement is used in a script file is shown in Sample Problem 6-2.

Sample Problem 6-2: Calculating worker's pay

A worker is paid according to his hourly wage up to 40 hours, and 50% more for overtime. Write a program in a script file that calculates the pay to a worker. The program asks the user to enter the number of hours and the hourly wage. The program then displays the pay.

Solution

The program in a script file is shown below. The program first calculates the pay by multiplying the number of hours by the hourly wage. Then an `if` statement checks whether the number of hours is greater than 40. If so, the next line is executed and the extra pay for the hours above 40 is added. If not, the program skips to the `end`.

```

t=input('Please enter the number of hours worked ');
h=input('Please enter the hourly wage in $ ');
Pay=t*h;
if t>40

```

```

    Pay=Pay+(t-40)*0.5*h;
end
fprintf('The worker's pay is $ %5.2f',Pay)

```

Application of the program (in the Command Window) for two cases is shown below (the file was saved as Workerpay):

```

>> Workerpay
Please enter the number of hours worked  35
Please enter the hourly wage in $      8
The worker's pay is $ 280.00
>> Workerpay
Please enter the number of hours worked  50
Please enter the hourly wage in $     10
The worker's pay is $ 550.00

```

6.2.2 The if-else-end Structure

The if-else-end structure provides a means for choosing one group of commands, out of a possible two groups, for execution. The if-else-end structure is shown in Figure 6-2. The figure shows how the commands are typed in the program, and a flowchart that illustrates the flow, or the sequence, in which the

Figure 6-2: The structure of the if-else-end conditional statement.

commands are executed. The first line is an `if` statement with a conditional expression. If the conditional expression is true, the program executes group 1 of commands between the `if` and the `else` statements and then skips to the `end`. If the conditional expression is false, the program skips to the `elseif` and then executes group 2 of commands between the `elseif` and the `end`.

6.2.3 The `if-elseif-else-end` Structure

The `if-elseif-else-end` structure is shown in Figure 6-3. The figure shows how the commands are typed in the program, and gives a flowchart that illustrates the flow, or the sequence, in which the commands are executed. This structure includes two conditional statements (`if` and `elseif`) that make it possible to select one out of three groups of commands for execution. The first line is an `if` statement with a conditional expression. If the conditional expression is true, the program executes group 1 of commands between the `if` and the

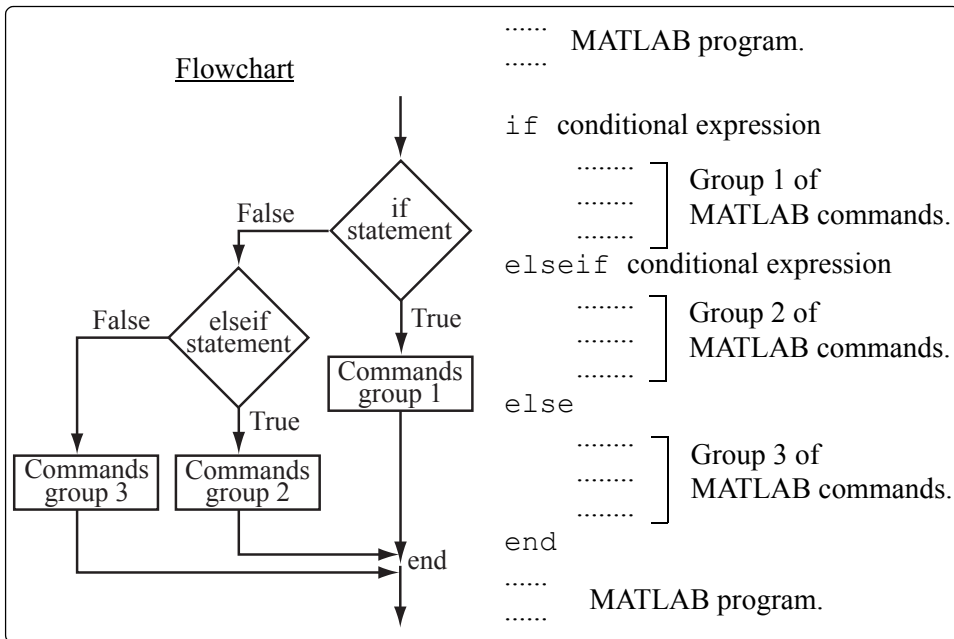

Figure 6-3: The structure of the `if-elseif-else-end` conditional statement.

`elseif` statements and then skips to the `end`. If the conditional expression in the `if` statement is false, the program skips to the `elseif` statement. If the conditional expression in the `elseif` statement is true, the program executes group 2 of commands between the `elseif` and the `else` and then skips to the `end`. If the conditional expression in the `elseif` statement is false, the program skips to the `else` and executes group 3 of commands between the `else` and the `end`.

It should be pointed out here that several `elseif` statements and associ-

ated groups of commands can be added. In this way more conditions can be included. Also, the `else` statement is optional. This means that in the case of several `elseif` statements and no `else` statement, if any of the conditional statements is true the associated commands are executed; otherwise nothing is executed.

The following example uses the `if-elseif-else-end` structure in a program.

Sample Problem 6-3: Water level in water tower

The tank in a water tower has the geometry shown in the figure (the lower part is a cylinder and the upper part is an inverted frustum of a cone). Inside the tank there is a float that indicates the level of the water. Write a MATLAB program that determines the volume of the water in the tank from the position (height h) of the float. The program asks the user to enter a value of h in m, and as output displays the volume of the water in m^3 .

Solution

For $0 \leq h \leq 19$ m the volume of the water is given by the volume of a cylinder with height h : $V = \pi 12.5^2 h$.

For $19 < h \leq 33$ m the volume of the water is given by adding the volume of a cylinder with $h = 19$ m, and the volume of the water in the cone:

$$V = \pi 12.5^2 \cdot 19 + \frac{1}{3} \pi (h - 19) (12.5^2 + 12.5 \cdot r_h + r_h^2)$$

where $r_h = 12.5 + \frac{10.5}{14}(h - 19)$.

The program is:

```
% The program calculates the volume of the water in the
water tower.
h=input('Please enter the height of the float in meter ');
if h > 33
    disp('ERROR. The height cannot be larger than 33 m.')
elseif h < 0
    disp('ERROR. The height cannot be a negative number.')
elseif h <= 19
    v = pi*12.5^2*h;
    fprintf('The volume of the water is %7.3f cubic meter.\n',v)
```

```
else
    rh=12.5+10.5*(h-19)/14;
    v=pi*12.5^2*19+pi*(h-19)*(12.5^2+12.5*rh+rh^2)/3;
    fprintf('The volume of the water is %7.3f cubic meter.\n',v)
end
```

The following is the display in the Command Window when the program is used with three different values of water height.

```
Please enter the height of the float in meter 8
The volume of the water is 3926.991 cubic meter.
Please enter the height of the float in meter 25.7
The volume of the water is 14114.742 cubic meter.
Please enter the height of the float in meter 35
ERROR. The height cannot be larger than 33 m.
```

6.3 THE switch-case STATEMENT

The switch-case statement is another method that can be used to direct the flow of a program. It provides a means for choosing one group of commands for execution out of several possible groups. The structure of the statement is shown in Figure 6-4.

- The first line is the `switch` command, which has the form:

`switch switch expression`

The switch expression can be a scalar or a string. Usually it is a variable that has an assigned scalar or a string. It can also be, however, a mathematical expression that includes pre-assigned variables and can be evaluated.

- Following the `switch` command are one or several `case` commands. Each has a value (can be a scalar or a string) next to it (`value1`, `value2`, etc.) and an associated group of commands below it.
- After the last `case` command there is an optional `otherwise` command followed by a group of commands.
- The last line must be an `end` statement.

How does the switch-case statement work?

The value of the switch expression in the `switch` command is compared with the values that are next to each of the `case` statements. If a match is found, the group of commands that follow the `case` statement with the match are executed. (Only one group of commands—the one between the `case` that matches and either the

```

.....  MATLAB program.
.....

switch switch expression
    case value1
        .....      ] Group 1 of commands.
        .....
    case value2
        .....      ] Group 2 of commands.
        .....
    case value3
        .....      ] Group 3 of commands.
        .....
    otherwise
        .....      ] Group 4 of commands.
        .....
end
.....  MATLAB program.
.....

```

Figure 6-4: The structure of a switch-case statement.

case, otherwise, or end statement that is next—is executed).

- If there is more than one match, only the first matching case is executed.
- If no match is found and the otherwise statement (which is optional) is present, the group of commands between otherwise and end is executed.
- If no match is found and the otherwise statement is not present, none of the command groups is executed.
- A case statement can have more than one value. This is done by typing the values in the form: {value1, value2, value3, ...}. (This form, which is not covered in this book, is called a cell array.) The case is executed if at least one of the values matches the value of switch expression.

A Note: In MATLAB only the first matching case is executed. After the group of commands associated with the first matching case are executed, the program skips to the end statement. This is different from the C language, where break statements are required.

Sample Problem 6-4: Converting units of energy

Write a program in a script file that converts a quantity of energy (work) given in units of either joule, ft-lb, cal, or eV to the equivalent quantity in different units specified by the user. The program asks the user to enter the quantity of energy, its

current units, and the desired new units. The output is the quantity of energy in the new units.

The conversion factors are: $1 \text{ J} = 0.738 \text{ ft-lb} = 0.239 \text{ cal} = 6.24 \times 10^{18} \text{ eV}$.

Use the program to:

- (a) Convert 150 J to ft-lb.
- (b) Convert 2,800 cal to J.
- (c) Convert 2.7 eV to cal.

Solution

The program includes two sets of switch-case statements and one if-else-end statement. The first switch-case statement is used to convert the input quantity from its initial units to units of joules. The second is used to convert the quantity from joules to the specified new units. The if-else-end statement is used to generate an error message if units are entered incorrectly.

```

Ein=input('Enter the value of the energy (work) to be converted: ');
EinUnits=input('Enter the current units (J, ft-lb, cal, or eV): ','s');
EoutUnits=input('Enter the new units (J, ft-lb, cal, or eV): ','s');
error=0;
switch EinUnits
case 'J'
    EJ=Ein;
case 'ft-lb'
    EJ=Ein/0.738;
case 'cal'
    EJ=Ein/0.239;
case 'eV'
    EJ=Ein/6.24e18;
otherwise
    error=1;
end
switch EoutUnits
case 'J'
    Eout=EJ;
case 'ft-lb'
    Eout=EJ*0.738;
case 'cal'
    Eout=EJ*0.239;
case 'eV'
    Eout=EJ*6.24e18;

```

Assign 0 to variable error.

First switch statement. Switch expression is a string with initial units.

Each of the four case statements has a value (string) that corresponds to one of the initial units, and a command that converts Ein to units of J. (Assign the value to EJ.)

Assign 1 to error if no match is found. Possible only if initial units were typed incorrectly.

Second switch statement. Switch expression is a string with new units.

Each of the four case statements has a value (string) that corresponds to one of the new units, and a command that converts EJ to the new units. (Assign the value to Eout.)

```

otherwise
    error=1;
end
if error
    disp('ERROR current or new units are typed incorrectly.')
else
    fprintf('E = %g %s',Eout,EoutUnits)
end

```

Assign 1 to error if no match is found. Possible only if new units were typed incorrectly.

If-else-end statement.

If error is true (nonzero), display an error message.

If error is false (zero), display converted energy.

As an example, the script file (saved as EnergyConversion) is used next in the Command Window to make the conversion in part (b) of the problem statement.

```

>> EnergyConversion
Enter the value of the energy (work) to be converted: 2800
Enter the current units (J, ft-lb, cal, or eV): cal
Enter the new units (J, ft-lb, cal, or eV): J
E = 11715.5 J

```

6.4 LOOPS

A loop is another method to alter the flow of a computer program. In a loop, the execution of a command, or a group of commands, is repeated several times consecutively. Each round of execution is called a pass. In each pass at least one variable, but usually more than one, or even all the variables that are defined within the loop, are assigned new values. MATLAB has two kinds of loops. In *for-end* loops (Section 6.4.1) the number of passes is specified when the loop starts. In *while-end* loops (Section 6.4.2) the number of passes is not known ahead of time, and the looping process continues until a specified condition is satisfied. Both kinds of loops can be terminated at any time with the *break* command (see Section 6.6).

6.4.1 for-end Loops

In *for-end* loops the execution of a command, or a group of commands, is repeated a predetermined number of times. The form of a loop is shown in Figure 6-5.

- The loop index variable can have any variable name (usually *i*, *j*, *k*, *m*, and *n* are used, however, *i* and *j* should not be used if MATLAB is used with complex numbers).

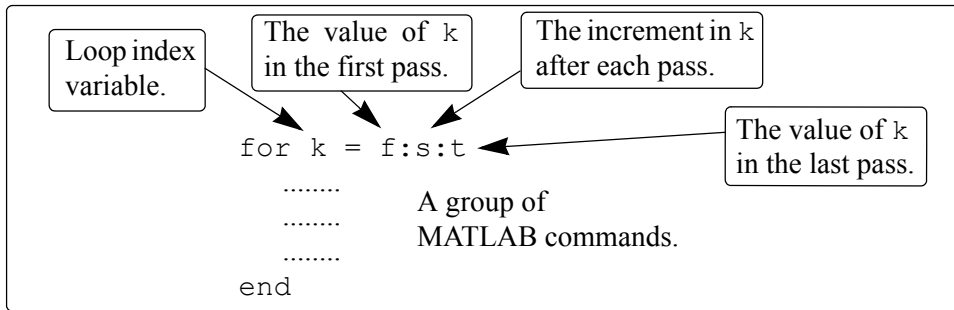

Figure 6-5: The structure of a `for-end` loop.

- In the first pass $k = f$ and the computer executes the commands between the `for` and `end` commands. Then, the program goes back to the `for` command for the second pass. k obtains a new value equal to $k = f + s$, and the commands between the `for` and `end` commands are executed with the new value of k . The process repeats itself until the last pass, where $k = t$. Then the program does not go back to the `for`, but continues with the commands that follow the `end` command. For example, if $k = 1:2:9$, there are five loops, and the corresponding values of k are 1, 3, 5, 7, and 9.
- The increment s can be negative (i.e.; $k = 25:-5:10$ produces four passes with $k = 25, 20, 15, 10$).
- If the increment value s is omitted, the value is 1 (default) (i.e.; $k = 3:7$ produces five passes with $k = 3, 4, 5, 6, 7$).
- If $f = t$, the loop is executed once.
- If $f > t$ and $s > 0$, or if $f < t$ and $s < 0$, the loop is not executed.
- If the values of k , s , and t are such that k cannot be equal to t , then if s is positive, the last pass is the one where k has the largest value that is smaller than t (i.e., $k = 8:10:50$ produces five passes with $k = 8, 18, 28, 38, 48$). If s is negative, the last pass is the one where k has the smallest value that is larger than t .
- In the `for` command k can also be assigned a specific value (typed as a vector). Example: `for k = [7 9 -1 3 3 5]`.
- The value of k should not be redefined within the loop.
- Each `for` command in a program *must* have an `end` command.
- The value of the loop index variable (k) is not displayed automatically. It is possible to display the value in each pass (which is sometimes useful for debugging) by typing k as one of the commands in the loop.

- When the loop ends, the loop index variable (k) has the value that was last assigned to it.

A simple example of a `for-end` loop (in a script file) is:

```
for k=1:3:10
    x = k^2
end
```

When this program is executed, the loop is executed four times. The value of k in the four passes is $k = 1, 4, 7$, and 10 , which means that the values that are assigned to x in the passes are $x = 1, 16, 49$, and 100 , respectively. Since a semicolon is not typed at the end of the second line, the value of x is displayed in the Command Window at each pass. When the script file is executed, the display in the Command Window is:

```
>> x =
     1
x =
    16
x =
    49
x =
   100
```

Sample Problem 6-5: Sum of a series

- (a) Use a `for-end` loop in a script file to calculate the sum of the first n terms of

the series: $\sum_{k=1}^n \frac{(-1)^k k}{2^k}$. Execute the script file for $n = 4$ and $n = 20$.

- (b) The function $\sin(x)$ can be written as a Taylor series by:

$$\sin x = \sum_{k=0}^{\infty} \frac{(-1)^k x^{2k+1}}{(2k+1)!}$$

Write a user-defined function file that calculates $\sin(x)$ by using the Taylor series. For the function name and arguments use $y = \text{Tsin}(x, n)$. The input arguments are the angle x in degrees and n the number of terms in the series. Use the function to calculate $\sin(150^\circ)$ using three and seven terms.

Solution

- (a) A script file that calculates the sum of the first n terms of the series is shown below.

The summation is done with a loop. In each pass one term of the series is calcu-

```

n=input('Enter the number of terms ' );
S=0;
for k=1:n
    S=S+(-1)^k*k/2^k;
end
fprintf('The sum of the series is: %f',S)

```

Setting the sum to zero.

for-end loop.

In each pass one element of the series is calculated and is added to the sum of the elements from the previous passes.

lated (in the first pass the first term, in the second pass the second term, and so on) and is added to the sum of the previous elements. The file is saved as Exp6_5a and then executed twice in the Command Window:

```

>> Exp6_5a
Enter the number of terms 4
The sum of the series is: -0.125000
>> Exp7_5a
Enter the number of terms 20
The sum of the series is: -0.222216

```

(b) A user-defined function file that calculates $\sin(x)$ by adding n terms of a Taylor series is shown below.

```

function y = Tsin(x,n)
% Tsin calculates the sin using Taylor formula.
% Input arguments:
% x The angle in degrees, n number of terms.

xr=x*pi/180;
y=0;
for k=0:n-1
    y=y+(-1)^k*xr^(2*k+1)/factorial(2*k+1);
end

```

Converting the angle from degrees to radians.

for-end loop.

The first element corresponds to $k = 0$, which means that in order to add n terms of the series, in the last loop $k = n - 1$. The function is used in the Command Window to calculate $\sin(150^\circ)$ using three and seven terms:

```

>> Tsin(150,3)
ans =
    0.6523

```

Calculating $\sin(150^\circ)$ with three terms of Taylor series.

```
>> Tsin(150,7)
```

Calculating $\sin(150^\circ)$ with seven terms of Taylor series.

```
ans =
```

The exact value is 0.5.

```
0.5000
```

A note about `for`-end loops and element-by-element operations:

In some situations the same end result can be obtained by either using `for`-end loops or using element-by-element operations. Sample Problem 6-5 illustrates how the `for`-end loop works, but the problem can also be solved by using element-by-element operations (see Problems 7 and 8 in Section 3.9). Element-by-element operations with arrays are one of the superior features of MATLAB that provide the means for computing in circumstances that otherwise require loops. In general, element-by-element operations are faster than loops and are recommended when either method can be used.

Sample Problem 6-6: Modify vector elements

A vector is given by $V = [5, 17, -3, 8, 0, -7, 12, 15, 20, -6, 6, 4, -7, 16]$. Write a program as a script file that doubles the elements that are positive and are divisible by 3 or 5, and, raises to the power of 3 the elements that are negative but greater than -5 .

Solution

The problem is solved by using a `for`-end loop that has an `if`-`elseif`-end conditional statement inside. The number of passes is equal to the number of elements in the vector. In each pass one element is checked by the conditional statement. The element is changed if it satisfies the conditions in the problem statement. A program in a script file that carries out the required operations is:

```
V=[5, 17, -3, 8, 0, -7, 12, 15, 20 -6, 6, 4, -2, 16];
n=length(V);
```

Setting n to be equal to the number of elements in V.

```
for k=1:n
```

for-end loop.

```
    if V(k)>0 & (rem(V(k),3) == 0 | rem(V(k),5) == 0)
```

if-elseif-end statement.

```
        V(k)=2*V(k);
    elseif V(k) < 0 & V(k) > -5
        V(k)=V(k)^3;
    end
end
V
```

The file is saved as Exp7_6 and then executed in the Command Window:

```
>> Exp7_6  
v =  
    10    17   -27     8     0    -7    24    30    40    -6    12     4  
   -8    16
```

6.4.2 while-end Loops

while-end loops are used in situations when looping is needed but the number of passes is not known in advance. In while-end loops the number of passes is not specified when the looping process starts. Instead, the looping process continues until a stated condition is satisfied. The structure of a while-end loop is shown in Figure 6-6.

```
while conditional expression  
    .....  
    ..... A group of  
    ..... MATLAB commands.  
end
```

Figure 6-6: The structure of a while-end loop.

The first line is a while statement that includes a conditional expression. When the program reaches this line the conditional expression is checked. If it is false (0), MATLAB skips to the end statement and continues with the program. If the conditional expression is true (1), MATLAB executes the group of commands that follow between the while and end commands. Then MATLAB jumps back to the while command and checks the conditional expression. This looping process continues until the conditional expression is false.

For a while-end loop to execute properly:

- The conditional expression in the while command must include at least one variable.
- The variables in the conditional expression must have assigned values when MATLAB executes the while command for the first time.
- At least one of the variables in the conditional expression must be assigned a new value in the commands that are between the while and the end. Otherwise, once the looping starts it will never stop since the conditional expression will remain true.

An example of a simple while-end loop is shown in the following program. In

this program a variable x with an initial value of 1 is doubled in each pass as long as its value is equal to or smaller than 15.

```
x=1
while x<=15
    x=2*x
end
```

Initial value of x is 1.

The next command is executed only if $x \leq 15$.

In each pass x doubles.

When this program is executed the display in the Command Window is:

```
x =
    1
x =
    2
x =
    4
x =
    8
x =
   16
```

Initial value of x .

In each pass x doubles.

When $x = 16$, the conditional expression in the `while` command is false and the looping stops.

Important note:

When writing a `while-end` loop, the programmer has to be sure that the variable (or variables) that are in the conditional expression and are assigned new values during the looping process will eventually be assigned values that make the conditional expression in the `while` command false. Otherwise the looping will continue indefinitely (indefinite loop). In the example above if the conditional expression is changed to $x >= 0.5$, the looping will continue indefinitely. Such a situation can be avoided by counting the passes and stopping the looping if the number of passes exceeds some large value. This can be done by adding the maximum number of passes to the conditional expression, or by using the `break` command (Section 6.6).

Since no one is free from making mistakes, a situation of indefinite looping can occur in spite of careful programming. If this happens, the user can stop the execution of an indefinite loop by pressing the **Ctrl + C** or **Ctrl + Break** keys.

Sample Problem 6-7: Taylor series representation of a function

The function $f(x) = e^x$ can be represented in a Taylor series by $e^x = \sum_{n=0}^{\infty} \frac{x^n}{n!}$.

Write a program in a script file that determines e^x by using the Taylor series representation. The program calculates e^x by adding terms of the series and stopping

when the absolute value of the term that was added last is smaller than 0.0001. Use a `while`-`end` loop, but limit the number of passes to 30. If in the 30th pass the value of the term that is added is not smaller than 0.0001, the program stops and displays a message that more than 30 terms are needed.

Use the program to calculate e^2 , e^{-4} , and e^{21} .

Solution

The first few terms of the Taylor series are:

$$e^x = 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \dots$$

A program that uses the series to calculate the function is shown next. The program asks the user to enter the value of x . Then the first term, a_n , is assigned the number 1, and a_n is assigned to the sum S . Then, from the second term on, the program uses a `while` loop to calculate the n th term of the series and add it to the sum. The program also counts the number of terms n . The conditional expression in the `while` command is true as long as the absolute value of the n th a_n term is larger than 0.0001, and the number of passes n is smaller than 30. This means that if the 30th term is not smaller than 0.0001, the looping stops.

```
x=input('Enter x ');
n=1; an=1; S=an;
while abs(an) >= 0.0001 & n <= 30
    an=x^n/factorial(n);
    S=S+an;
    n=n+1;
end
if n >= 30
    disp('More than 30 terms are needed')
else
    fprintf('exp(%f) = %f',x,S)
    fprintf('\nThe number of terms used is: %i',n)
end
```

Start of the `while` loop.

Calculating the n th term.

Adding the n th term to the sum.

Counting the number of passes.

End of the `while` loop.

`if-else-end` loop.

The program uses an `if-else-end` statement to display the results. If the looping stopped because the 30th term is not smaller than 0.0001, it displays a message indicating this. If the value of the function is calculated successfully, it displays the value of the function and the number of terms used. When the program executes, the number of passes depends on the value of x . The program (saved as `expox`) is used to calculate e^2 , e^{-4} , and e^{21} :

```
>> expox
```

Sample Problem 6-8: Creating a matrix with a loop

Write a program in a script file that creates an $n \times m$ matrix with elements that have the following values. The value of each element in the first row is the number of the column. The value of each element in the first column is the number of the row. The rest of the elements each has a value equal to the sum of the element above it and the element to the left. When executed, the program asks the user to enter values for n and m .

Solution

The program, shown below, has two loops (one nested) and a nested if-elseif-else-end structure. The elements in the matrix are assigned values row by row. The loop index variable of the first loop, k , is the address of the row, and the loop index variable of the second loop, h , is the address of the column.

```
n=input('Enter the number of rows ');
m=input('Enter the number of columns ');
A=[];
for k=1:n
    for h=1:m
        if k==1
            A(k,h)=h;
        elseif h==1
            A(k,h)=k;
        else
            A(k,h)=A(k,h-1)+A(k-1,h);
        end
    end
end
A
```

Define an empty matrix A

Start of the first for-end loop.

Start of the second for-end loop.

Start of the conditional statement.

Assign values to the elements of the first row.

Assign values to the elements of the first column.

Assign values to other elements.

end of the if statement.

end of the nested for-end loop.

end of the first for-end loop.

The program is executed in the Command Window to create a 4×5 matrix.

```
>> Chap6_exp8
Enter the number of rows 4
Enter the number of columns 5
```

A =				
	1	2	3	4
	2	4	7	11
	3	7	14	25
	4	11	25	50
				91

6.6 THE *break* AND *continue* COMMANDS

The *break* command:

- When inside a loop (*for* or *while*), the *break* command terminates the execution of the loop (the whole loop, not just the last pass). When the *break* command appears in a loop, MATLAB jumps to the *end* command of the loop and continues with the next command (it does not go back to the *for* command of that loop).
- If the *break* command is inside a nested loop, only the nested loop is terminated.
- When a *break* command appears outside a loop in a script or function file, it terminates the execution of the file.
- The *break* command is usually used within a conditional statement. In loops it provides a method to terminate the looping process if some condition is met—for example, if the number of loops exceeds a predetermined value, or an error in some numerical procedure is smaller than a predetermined value. When typed outside a loop, the *break* command provides a means to terminate the execution of a file, such as when data transferred into a function file is not consistent with what is expected.

The *continue* command:

- The *continue* command can be used inside a loop (*for* or *while*) to stop the present pass and start the next pass in the looping process.
- The *continue* command is usually a part of a conditional statement. When MATLAB reaches the *continue* command, it does not execute the remaining commands in the loop, but skips to the *end* command of the loop and then starts a new pass.

6.7 EXAMPLES OF MATLAB APPLICATIONS

Sample Problem 6-9: Withdrawing from a retirement account.

A person in retirement is depositing \$300,000 in a saving account that pays 5% interest per year. The person plans to withdraw money from the account once a year. He starts by withdrawing \$25,000 after the first year, and in future years he increases the amount he withdraws according to the inflation rate. For example, if the inflation rate is 3%, he withdraws \$25,750 after the second year. Calculate the number of years the money in the account will last assuming a constant yearly inflation rate of 2%. Make a plot that shows the yearly withdrawals and the balance of the account over the years.

Solution

The problem is solved by using a loop (a `while` loop since the number of passes is not known before the loop starts). In each pass the amount to be withdrawn and the account balance are calculated. The looping continues as long as the account balance is larger than or equal to the amount to be withdrawn. The following is a program in a script file that solves the problem. In the program, `year` is a vector in which each element is a year number, `W` is a vector with the amount withdrawn each year, and `AB` is a vector with the account balance each year.

```
rate=0.05; inf=0.02;
clear W AB year
year(1)=0;
W(1)=0;
AB(1)=300000;
Wnext=25000;
ABnext=300000*(1 + rate);
n=2;
    while ABnext >= Wnext
        year(n)=n-1;
        W(n)=Wnext;
        AB(n)=ABnext-W(n);
        ABnext=AB(n)*(1+rate);
        Wnext=W(n)*(1+inf);
        n=n+1;
    end
fprintf('The money will last for %f years',year(n-1))
bar(year,[AB' W'],2.0)
```

First element is year 0.

Initial withdrawal amount.

Initial account balance.

The amount to be withdrawn after a year.

The account balance after a year.

`while` checks if the next balance is larger than the next withdrawal.

Amount withdrawn in year $n - 1$.

Account balance in year $n - 1$ after withdrawal.

The account balance after additional year.

The amount to be withdrawn after an additional year.

The program is executed in the following Command Window:

```
>> Chap6_exp9
```

```
The money will last for 15 years.
```

The program also generates the following figure (axis labels and legend were added to the plot by using the Plot Editor).

Sample Problem 6-10: Creating a random list

Six singers—John, Mary, Tracy, Mike, Katie, and David—are performing in a competition. Write a MATLAB program that generates a list of a random order in which the singers will perform.

Solution

An integer (1 through 6) is assigned to each name (1 to John, 2 to Mary, 3 to Tracy, 4 to Mike, 5 to Katie, and 6 to David). The program, shown below, first creates a list of the integers 1 through 6 in a random order. The integers are made the elements of six-element vector. This is done by using MATLAB's built-in function `randi` (see Section 3.7) for assigning integers to the elements of the vector. To make sure that all the integers of the elements are different from each other, the integers are assigned one by one. Each integer that is suggested by the `randi` function is compared with all the integers that have been assigned to previous elements. If a match is found, the integer is not assigned, and `randi` is used for suggesting a new integer. Since each singer name is associated with an integer, once the integer list is complete the `switch-case` statement is used to create the corresponding name list.

```
clear, clc
n=6;
```

```

L(1)=randi(n);
for p=2:n
    L(p)=randi(n);
    r=0;
    while r==0
        r=1;
        for k=1:p-1
            if L(k)==L(p)
                L(p)=randi(n);
                r=0;
                break
            end
        end
    end
end
for i=1:n
    switch L(i)
    case 1
        disp('John')
    case 2
        disp('Mary')
    case 3
        disp('Tracy')
    case 4
        disp('Mike')
    case 5
        disp('Katie')
    case 6
        disp('David')
    end
end

```

Assign the first integer to $L(1)$.

Assign the next integer to $L(p)$.

Set r to zero.

See explanation below.

Set r to 1.

for loop compares the integer assigned to $L(p)$ to the integers that have been assigned to previous elements.

If a match is found, a new integer is assigned to $L(p)$ and r is set to zero.

The nested for loop is stopped. The program goes back to the while loop. Since $r = 0$ the nested loop inside the while loop starts again and checks if the new integer that is assigned to $L(p)$ is equal to an integer that is already in the vector L .

The switch-case statement lists the names according to the values of the integers in the elements of L .

The while loop checks that every new integer (element) that is to be added to the vector L is not equal any of the integers in elements already in the vector L . If a match is found, it keeps generating new integers until the new integer is different from all the integers that are already in x .

When the program is executed, the following is displayed in the Command Window. Obviously, a list in a different order will be displayed every time the program is executed.

The performing order is:

Katie
Tracy
David
Mary
John
Mike

Sample Problem 6-11: Flight of a model rocket

The flight of a model rocket can be modeled as follows. During the first 0.15 s the rocket is propelled upward by the rocket engine with a force of 16 N. The rocket then flies up while slowing down under the force of gravity. After it reaches the apex, the rocket starts to fall back down. When its downward velocity reaches 20 m/s a parachute opens (assumed to open instantly), and the rocket continues to drop at a constant speed of 20 m/s until it hits the ground. Write a program that calculates and plots the speed and altitude of the rocket as a function of time during the flight.

Solution

The rocket is assumed to be a particle that moves along a straight line in the vertical plane. For motion with constant acceleration along a straight line, the velocity and position as a function of time are given by:

$$v(t) = v_0 + at \quad \text{and} \quad s(t) = s_0 + v_0t + \frac{1}{2}at^2$$

where v_0 and s_0 are the initial velocity and position, respectively. In the computer program the flight of the rocket is divided into three segments. Each segment is calculated in a `while` loop. In every pass the time increases by an increment.

Segment 1: The first 0.15 s when the rocket engine is on. During this period, the rocket moves up with a constant acceleration. The acceleration is determined by drawing a free body and a mass acceleration diagram (shown on the right). From Newton's second law, the sum of the forces in the vertical direction is equal to the mass times the acceleration (equilibrium equation):

$$+\uparrow \Sigma F = F_E - mg = ma$$

Solving the equation for the acceleration gives:

$$a = \frac{F_E - mg}{m}$$

The velocity and height as a function of time are:

$$v(t) = 0 + at \quad \text{and} \quad h(t) = 0 + 0 + \frac{1}{2}at^2$$

where the initial velocity and initial position are both zero. In the computer program this segment starts at $t = 0$, and the looping continues as long as $t < 0.15$ s. The time, velocity, and height at the end of this segment are t_1 , v_1 , and h_1 .

Segment 2: The motion from when the engine stops until the parachute opens. In this segment the rocket moves with a constant deceleration g . The speed and height of the rocket as functions of time are given by:

$$v(t) = v_1 - g(t - t_1) \quad \text{and} \quad h(t) = h_1 + v_1(t - t_1) - \frac{1}{2}g(t - t_1)^2$$

In this segment the looping continues until the velocity of the rocket is -20 m/s (negative since the rocket moves down). The time and height at the end of this segment are t_2 and h_2 .

Segment 3: The motion from when the parachute opens until the rocket hits the ground. In this segment the rocket moves with constant velocity (zero acceleration). The height as a function of time is given by $h(t) = h_2 - v_{chute}(t - t_2)$, where v_{chute} is the constant velocity after the parachute opens. In this segment the looping continues as long as the height is greater than zero.

A program in a script file that carries out the calculations is shown below.

```
m=0.05; g=9.81; tEngine=0.15; Force=16; vChute=-20; Dt=0.01;
clear t v h
n=1;
t(n)=0; v(n)=0; h(n)=0;
% Segment 1
a1=(Force-m*g)/m;
while t(n) < tEngine & n < 50000
    n=n+1;
    t(n)=t(n-1)+Dt;
    v(n)=a1*t(n);
    h(n)=0.5*a1*t(n)^2;
end
v1=v(n); h1=h(n); t1=t(n);
% Segment 2
while v(n) >= vChute & n < 50000
    n=n+1;
    t(n)=t(n-1)+Dt;
    v(n)=v1-g*(t(n)-t1);
```

The first while loop.

The second while loop.

```

    h(n)=h1+v1*(t(n)-t1)-0.5*g*(t(n)-t1)^2;
end
v2=v(n); h2=h(n); t2=t(n);
% Segment 3
while h(n) > 0 & n < 50000
    n=n+1;
    t(n)=t(n-1)+Dt;
    v(n)=vChute;
    h(n)=h2+vChute*(t(n)-t2);
end
subplot(1,2,1)
plot(t,h,t2,h2,'o')
subplot(1,2,2)
plot(t,v,t2,v2,'o')

```

The third while loop.

The accuracy of the results depends on the magnitude of the time increment Δt . An increment of 0.01 s appears to give good results. The conditional expression in the `while` commands also includes a condition for n (if n is larger than 50,000 the loop stops). This is done as a precaution to avoid an infinite loop in case there is an error in any of the statements inside the loop. The plots generated by the program are shown below (axis labels and text were added to the plots using the Plot Editor).

Note: The problem can be solved and programmed in different ways. The solution shown here is one option. For example, instead of using `while` loops, the times when the parachute opens and when the rocket hits the ground can be calculated first, and then `for-end` loops can be used instead of the `while` loop. If the times are determined first, it is possible also to use element-by-element calculations instead of loops.

Sample Problem 6-12: AC to DC converter

A half-wave diode rectifier is an electrical circuit that converts AC voltage to DC voltage. A rectifier circuit that consists of an AC voltage source, a diode, a capacitor, and a load (resistor) is shown in the figure. The voltage of the source is $v_s = v_0 \sin(\omega t)$, where $\omega = 2\pi f$, in which f is the frequency. The operation of the circuit is illustrated in the lower diagram where the dashed line shows the source voltage and the solid line shows the voltage across the resistor. In the first cycle, the diode is on (conducting current) from $t = 0$ until $t = t_A$. At this time the diode turns off and the power to the resistor is supplied by the discharging capacitor. At $t = t_B$ the diode turns on again and continues to conduct current until $t = t_D$. The cycle continues as long as the voltage source is on. In this simplified analysis of this circuit, the diode is assumed to be ideal and the capacitor is assumed to have no charge initially (at $t = 0$). When the diode is on, the resistor's voltage and current are given by:

$$v_R = v_0 \sin(\omega t) \quad \text{and} \quad i_R = v_0 \sin(\omega t) / R$$

The current in the capacitor is:

$$i_C = \omega C v_0 \cos(\omega t)$$

When the diode is off, the voltage across the resistor is given by:

$$v_R = v_0 \sin(\omega t_A) e^{-(t-t_A)/(RC)}$$

The times when the diode switches off (t_A , t_D , and so on) are calculated from the condition $i_R = -i_C$. The diode switches on again when the voltage of the source reaches the voltage across the resistor (time t_B in the figure).

Write a MATLAB program that plots the voltage across the resistor v_R and the voltage of the source v_s as a function of time for $0 \leq t \leq 70$ ms. The resistance of the load is $1,800 \, \Omega$, the voltage source $v_0 = 12$ V, and $f = 60$ Hz. To examine the effect of capacitor size on the voltage across the load, execute the program twice, once with $C = 45 \, \mu\text{F}$ and once with $C = 10 \, \mu\text{F}$.

Solution

A program that solves the problem is presented below. The program has two parts—one that calculates the voltage v_R when the diode is on, and the other when the diode is off. The `switch` command is used for switching between the two parts. The calculations start with the diode on (the variable `state='on'`), and when $i_R - i_C \leq 0$ the value of `state` is changed to `'off'`, and the program switches to the commands that calculate v_R for this state. These calculations continue until $v_s \geq v_R$, when the program switches back to the equations that are valid when the diode is on.

```
V0=12; C=45e-6; R=1800; f=60;
Tf=70e-3; w=2*pi*f;
clear t VR Vs
t=0:0.05e-3:Tf;
n=length(t);
state='on'
for i=1:n
    Vs(i)=V0*sin(w*t(i));
    switch state
        case 'on'
            VR(i)=Vs(i);
            iR=Vs(i)/R;
            iC=w*C*V0*cos(w*t(i));
            sumI=iR+iC;
            if sumI <= 0
                state='off';
                tA=t(i);
            end
        case 'off'
            VR(i)=V0*sin(w*tA)*exp(-(t(i)-tA)/(R*C));
            if Vs(i) >= VR(i)
                state='on';
            end
    end
end
plot(t,Vs,':',t,VR,'k','linewidth',1)
xlabel('Time (s)'); ylabel('Voltage (V)')
```

Assign 'on' to the variable `state`.

Calculate the voltage of the source at time t .

Diode is on.

Check if $i_R - i_C \leq 0$.

If true, assign 'off' to `state`.

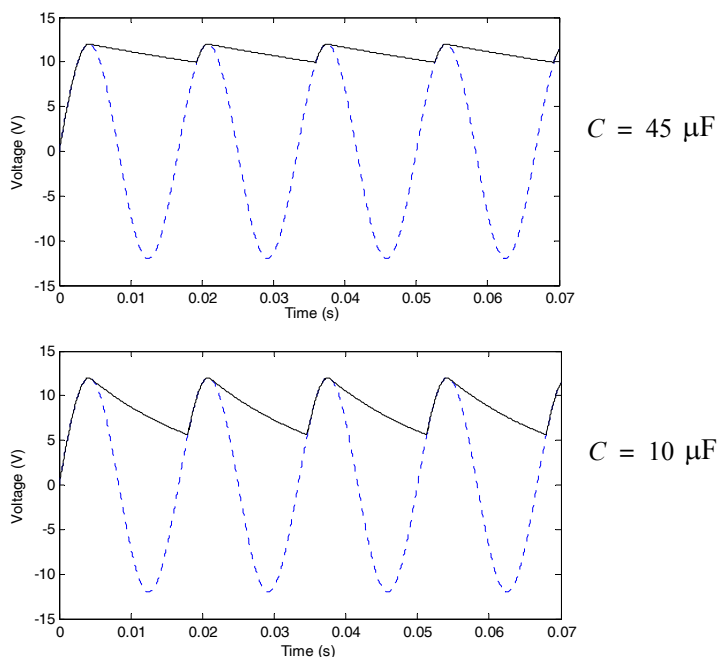

Assign a value to t_A .

Diode is off.

Check if $v_s \geq v_R$.

If true, assign 'on' to the variable `state`.

The two plots generated by the program are shown below. One plot shows the result with $C = 45 \mu\text{F}$ and the other with $C = 10 \mu\text{F}$. It can be observed that with a larger capacitor the DC voltage is smoother (smaller ripple in the wave).

6.8 PROBLEMS

1. Evaluate the following expressions without using MATLAB. Check the answer with MATLAB.

(a) $5 + 3 > 32/4$

(b) $y = 2 \times 3 > 10/5 + 1 > 2^2$

(c) $y = 2 \times (3 > 10/5) + (1 > 2)^2$

(d) $5 \times 3 - 4 \times 4 < \sim 2 \times 4 - 2 + \sim 0$

2. Given: $a = 6$, $b = 2$, $c = -5$. Evaluate the following expressions without using MATLAB. Check the answer with MATLAB.

(a) $y = a + b > a - b < c$

(b) $y = -6 < c < -2$

(c) $y = b + c > = c > a/b$

(d) $y = a + c = \sim (c + a \sim = a/b - b)$

3. Given: $v = [4 \ -2 \ -1 \ 5 \ 0 \ 1 \ -3 \ 8 \ 2]$ and $w = [0 \ 2 \ 1 \ -1 \ 0 \ -2 \ 4 \ 3 \ 2]$. Evaluate the following expressions without using MATLAB. Check the answer with MATLAB.

(a) $\sim(\sim v)$

(b) $u == v$

(c) $u - v < u$

(d) $u - (v < u)$

4. Use the vectors v and w from Problem 3. Use relational operators to create a vector y that is made up of the elements of w that are larger than or equal to the elements of v .
5. Evaluate the following expressions without using MATLAB. Check the answer with MATLAB.

(a) $0 \& 21$ (c) $4 - 7/2 \& 6 < 5 -3$	(b) $\sim 2 > -1 \& 11 > \sim 0$ (d) $3 -1 \& \sim 2 * -3 0$
--	---

6. The maximum daily temperature (in °F) for Chicago and San Francisco during the month of August 2009 are given in the vectors below (data from the U.S. National Oceanic and Atmospheric Administration).

TCH = [75 79 86 86 79 81 73 89 91 86 81 82 86 88 89 90 82 84 81 79 73 69 73 79 82 72 66 71 69 66 66]

TSF = [69 68 70 73 72 71 69 76 85 87 74 84 76 68 79 75 68 68 73 72 79 68 68 69 71 70 89 95 90 66 69]

Write a program in a script file to answer the following:

- (a) Calculate the average temperature for the month in each city.
 - (b) How many days was the temperature above the average in each city?
 - (c) How many days, and on which dates in the month, was the temperature in San Francisco lower than the temperature in Chicago?
 - (d) How many days, and on which dates in the month, was the temperature the same in both cities?
7. Fibonacci numbers are the numbers in a sequence in which the first two elements are 0 and 1, and the value of each subsequent element is the sum of the previous two elements:

0, 1, 1, 2, 3, 5, 8, 13, ...

Write a MATLAB program in a script file that determines and displays the first 20 Fibonacci numbers.

8. Use loops to create a 4×3 matrix in which the value of each element is the sum of its row number and its column number divided by the square of its column number. For example, the value of element (2,3) is $(2 + 3)/3^2 = 0.5555$.

9. The elements of the symmetric Pascal matrix are obtained from:

$$P_{ij} = \frac{(i+j-2)!}{(i-1)!(j-1)!}$$

Write a MATLAB program that creates an $n \times n$ symmetric Pascal matrix. Use the program to create 4×4 and 7×7 Pascal matrices.

10. A Fibonacci sequence is a sequence of numbers beginning with 0 and 1, where the value of each subsequent element is the sum of the previous two elements:

$$a_{i+1} = a_i + a_{i-1}, \text{ i.e. } 0, 1, 1, 2, 3, 5, 8, 13, \dots$$

Related sequences can be constructed with other beginning numbers. Write a MATLAB program in a script file that constructs an $n \times n$ matrix such that the first row contains the first n elements of a sequence, the second row contains the $n+1$ through $2n$ th elements and so on. The first line of the script should show the order n of the matrix followed by the values of the first two elements. These two elements can be any two integers, except they cannot both be zero. A property of matrices thus constructed is that their determinants are always zero. Run the program for $n = 4$ and $n = 6$ and for different values of the first two elements. Verify that the determinant is zero in each case (use MATLAB's built-in function `det`).

11. Write a program in a script file that determines the real roots of a quadratic equation $ax^2 + bx + c = 0$. Name the file `quadroots`. When the file runs, it asks the user to enter the values of the constants a , b , and c . To calculate the roots of the equation the program calculates the discriminant D , given by:

$$D = b^2 - 4ac$$

If $D > 0$, the program displays message "The equation has two roots," and the roots are displayed in the next line.

If $D = 0$, the program displays message "The equation has one root," and the root is displayed in the next line.

If $D < 0$, the program displays message "The equation has no real roots."

Run the script file in the Command Window three times to obtain solutions to the following three equations:

(a) $2x^2 + 8x + 8 = 0$

(b) $-5x^2 + 3x - 4 = 0$

(c) $-2x^2 + 7x + 4 = 0$

12. Write a program in a script file that finds the smallest odd integer that is divisible by 11 and whose square root is greater than 132. Use a loop in the program. The loop should start from 1 and stop when the number is found. The program prints the message "The required number is:" and then prints the number.

13. Write a program (using a loop) that determines the expression:

$$\sqrt{12} \sum_{n=0}^m \frac{(-1/3)^n}{2n+1}$$

Run the program with $m = 5$, $m = 10$, and $m = 20$. Compare the result with π . (Use `format long`.)

14. Write a program (using a loop) that determines the expression:

$$2 \prod_{n=1}^m \frac{(2n)^2}{(2n)^2 - 1} = 2 \left(\frac{4}{3} \cdot \frac{16}{15} \cdot \frac{36}{35} \cdot \dots \right)$$

Run the program with $m = 100$, $m = 100,000$, and $m = 1,000,000$. Compare the result with π . (Use format long.)

15. A vector is given by $x = [-3.5 \ -5 \ 6.2 \ 11 \ 0 \ 8.1 \ -9 \ 0 \ 3 \ -1 \ 3 \ 2.5]$. Using conditional statements and loops, write a program that creates two vectors from x —one (call it P) that contains the positive elements of x , and a second (call it N) that contains the negative elements of x . In both P and N , the elements are in the same order as in x .
16. A vector is given by $x = [-3.5 \ 5 \ -6.2 \ 11.1 \ 0 \ 7 \ -9.5 \ 2 \ 15 \ -1 \ 3 \ 2.5]$. Using conditional statements and loops, write a program that rearranges the elements of x in order from the smallest to the largest. Do not use MATLAB's built-in function `sort`.

17. The following is a list of 20 exam scores. Write a computer program that calculates the average of the top 8 scores.

Exam scores: 73, 91, 37, 81, 63, 66, 50, 90, 75, 43, 88, 80, 79, 69, 26, 82, 89, 99, 71, 59

18. The Taylor series expansion for $\sin(x)$ is

$$\sin(x) = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} + \dots = \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n+1)!} x^{2n+1}$$

where x is in radians. Write a MATLAB program that determines $\sin(x)$ using the Taylor series expansion. The program asks the user to type a value for an angle in degrees. Then the program uses a loop for adding the terms of the Taylor series. If a_n is the n th term in the series, then the sum S_n of the n terms is $S_n = S_{n-1} + a_n$. In each pass calculate the estimated error E given by

$$E = \left| \frac{S_n - S_{n-1}}{S_{n-1}} \right|$$

Stop adding terms when $E \leq 0.000001$. The program displays

the value of $\sin(x)$. Use the program for calculating:

(a) $\sin(45^\circ)$ (b) $\sin(195^\circ)$.

Compare the values with those obtained by using a calculator.

19. Write a MATLAB program in a script file that finds a positive integer n such that the sum of all the integers $1 + 2 + 3 + \dots + n$ is a number between 100 and 1000 whose three digits are identical. As output the program displays the integer n and the corresponding sum.

20. The following are formulas for calculating the training heart rate (*THR*) for men and women

For men (Karvonen formula): $THR = [(220 - AGE) - RHR] \times INTEN + RHR$

For women: $THR = [(206 - 0.88 \times AGE) - RHR] \times INTEN + RHR$

where *AGE* is the person's age, *RHR* the resting heart rate, and *INTEN* the fitness level (0.55 for low, 0.65 for medium, and 0.8 for high fitness). Write a program in a script file that determines the *THR*. The program asks users to enter their gender (male or female), age (number), resting heart rate (number), and fitness level (low, medium, or high). The program then displays the training heart rate. Use the program for determining the training heart rate for the following two individuals:

- (a) A 21-years-old male, resting heart rate of 62, and low fitness level.
- (b) A 19-years-old female, resting heart rate of 67, and high fitness level.

21. Write a program that determines the center and the radius of a circle that passes through three given points. The program asks the user to enter the coordinates of the points one at a time. The program displays the coordinate of the center and the radius, and makes a plot of the circle and the three points displayed on the plot with asterisk markers. Execute the program to find the circle that passes through the points (13, 15), (4, 18), and (19, 3).

22. Body Mass Index (*BMI*) is a measure of obesity. In standard units it is calculated by the formula

$$BMI = 703 \frac{W}{H^2}$$

where *W* is weight in pounds, and *H* is height in inches. The obesity classification is:

<i>BMI</i>	Classification
Below 18.5	Underweight
18.5 to 24.9	Normal
25 to 29.9	Overweight
30 and above	Obese

Write a program in a script file that calculates the *BMI* of a person. The program asks the person to enter his or her weight (lb) and height (in.). The program displays the result in a sentence that reads: "Your BMI value is XXX, which classifies you as SSSS," where XXX is the BMI value rounded to the nearest tenth, and SSSS is the corresponding classification. Use the program for determining the obesity of the following two individuals:

- (a) A person 6 ft 2 in. tall with a weight of 180 lb.
- (b) A person 5 ft 1 in. tall with a weight of 150 lb.

23. Write a program in a script file that calculates the cost of a telephone call according to the following price schedule:

Time the call made	Duration of call		
	1–10 min	10–30 min	More than 30 min
Day: 8 A.M. to 6 P.M.	\$0.10/min	\$1.00 + \$0.08/min for additional min above 10.	\$2.60 + \$0.06/min for additional min above 30.
Evening: 6 P.M. to 12 A.M.	\$0.07/min	\$0.70 + \$0.05/min for additional min above 10.	\$1.70 + \$0.04/min for additional min above 30.
Night: 12 A.M. to 8 A.M.	\$0.04/min	\$0.40 + \$0.03/min for additional min above 10.	\$1.00 + \$0.02/min for additional min above 13.

The program asks the user to enter the time the call is made (day, evening, or night) and the duration of the call (a number that can have one digit to the right of the decimal point). If the duration of the call is not an integer, the program rounds up the duration to the next integer. The program then displays the cost of the call.

Run the program three times for the following calls:

- (a) 8.3 min at 1:32 P.M. (b) 34.5 min at 8:00 P.M. (c) 29.6 min at 1:00 A.M.

24. Write a program that determines the change given back to a customer in a self-service checkout machine of a supermarket for purchases of up to \$20. The program generates a random number between 0.01 and 20.00 and displays the number as the amount to be paid. The program then asks the user to enter payment, which can be one \$1 bill, one \$5 bill, one \$10 bill, or one \$20 bill. If the payment is less than the amount to be paid, an error message is displayed. If the payment is sufficient, the program calculates the change and lists the bills and/or the coins that make up the change, which has to be composed of the least number each of bills and coins. For example, if the amount to be paid is \$2.33 and a \$10 bill is entered as payment, then the change is one \$5 bill, two \$1 bills, two quarters, one dime, one nickel, and two pennies.

25. The concentration of a drug in the body C_p can be modeled by the equation

$$C_p = \frac{D_G}{V_d(k_a - k_e)}(e^{-k_e t} - e^{-k_a t})$$

where D_G is the dosage administered (mg), V_d is the volume of distribution (L), k_a is the absorption rate constant (h^{-1}), k_e is the elimination rate constant (h^{-1}), and t is the time (h) since the drug was administered. For a certain drug, the following quantities are given: $D_G = 150$ mg, $V_d = 50$ L, $k_a = 1.6 \text{ h}^{-1}$, and $k_e = 0.4 \text{ h}^{-1}$.

- (a) A single dose is administered at $t = 0$. Calculate and plot C_p versus t for 10 hours.

(b) A first dose is administered at $t = 0$, and subsequently four more doses are administered at intervals of 4 hours (i.e., at $t = 4, 8, 12, 16$). Calculate and plot C_p versus t for 24 hours.

26. One numerical method for calculating the square root of a number is the Babylonian method. In this method \sqrt{P} is calculated in iterations. The solution process starts by choosing a value x_1 as a first estimate of the solution. Using this value, a second, more accurate solution x_2 can be calculated with $x_2 = (x_1 + P/x_1)/2$, which is then used for calculating a third, still more accurate solution x_3 , and so on. The general equation for calculating the value of the solution x_{i+1} from the solution x_i is $x_{i+1} = (x_i + P/x_i)/2$. Write a MATLAB program that calculates the square root of a number. In the program use $x = P$ for the first estimate of the solution. Then, by using the general equation in a loop, calculate new, more accurate solutions. Stop the looping when the estimated relative error E defined by $E = \left| \frac{x_{i+1} - x_i}{x_i} \right|$ is smaller than 0.00001. Use the program to calculate:

(a) $\sqrt{110}$

(b) $\sqrt{93,443}$

(c) $\sqrt{23.25}$

27. A twin primes is a pair of prime numbers such that the difference between them is 2 (for example, 17 and 19). Write a computer program that finds all the twin primes between 10 and 500. The program displays the results in a two-column matrix in which each row is a twin prime.
28. Write a program in a script file that converts a measure of volume given in units of either m^3 , L, ft^3 , or gal (U.S. gallons) to the equivalent quantity in different units specified by the user. The program asks the user to enter the amount of volume, its current units, and the desired new units. The output is the specification of volume in the new units. Use the program to:
- (a) Convert 3.5 m^3 to gal.
 (b) Convert 200 L to ft^3 .
 (c) Convert 480 ft^3 to m^3 .
29. In a one-dimensional random walk the position x of a walker is computed by

$$x_j = x_j + s$$

where s is a random number. Write a program that calculates the number of steps required for the walker to reach a boundary $x = \pm B$. Use MATLAB's built-in function `randn(1,1)` to calculate s . Run the program 100 times (by using a loop) and calculate the average number of steps when $B = 10$.

30. The Sierpinski triangle can be implemented in MATLAB by plotting points iteratively according to one of the following three rules which are selected randomly with equal probability.

Rule 1: $x_{n+1} = 0.5x_n$, $y_{n+1} = 0.5y_n$

Rule 2: $x_{n+1} = 0.5x_n + 0.25$, $y_{n+1} = 0.5y_n + \frac{\sqrt{3}}{4}$

Rule 3: $x_{n+1} = 0.5x_n + 0.5$, $y_{n+1} = 0.5y_n$

Write a program in a script file that calculates the x and y vectors and then plots y versus x as individual points (use `plot(x, y, 's')`). Start with $x_1 = 0$ and $y_1 = 0$. Run the program four times with 10, 100, 1,000, and 10,000 iterations.

31. There are 12 teams in a league, numbered 1 through 12. Six games are planned for the weekend. Write a MATLAB program that randomly assign the teams for each game. Display the results in a two-column table where each row contains the two teams that play each other.
32. The temperature dependence of the heat capacity C_p of many gases can be described in terms of a cubic equation:

$$C_p = a + bT + cT^2 + dT^3$$

The following table gives the coefficients of the cubic equation for four gases. C_p is in J/(g mol)(°C) and T is in °C.

Gas	a	b	c	d
SO ₂	38.91	3.904×10^{-2}	-3.105×10^{-5}	8.606×10^{-9}
SO ₃	48.50	9.188×10^{-2}	-8.540×10^{-5}	32.40×10^{-9}
O ₂	29.10	1.158×10^{-2}	-0.6076×10^{-5}	1.311×10^{-9}
N ₂	29.00	0.2199×10^{-2}	-0.5723×10^{-5}	-2.871×10^{-9}

Write a program that does the following:

- Prints the four gases on the screen and asks the user to select which gas to find the heat capacity for.
- Asks the user for a temperature.
- Asks the user if another temperature is needed (enter yes or no). If the answer is yes, the user is asked to enter another temperature. This process continues until the user enters no.
- Display a table containing the temperatures entered and the corresponding heat capacities.

- (a) Use the program for determining the heat capacity of SO_3 at 100° and 180° .
- (b) Use the program for finding the heat capacity of N_2 at 220° and 300° .

33. The overall grade in a course is determined from the grades of 5 quizzes, 3 midterms, and a final, using the following scheme:

Quizzes: Quizzes are graded on a scale from 0 to 10. The grade of the lowest quiz is dropped and the average of the 4 quizzes with the higher grades constitutes 25% of the course grade.

Midterms: Midterms are graded on a scale from 0 to 100. If the average of the midterm scores is higher than the score on the final, the average of the midterms is 35% of the course grade. If the final grade is higher than the average of the midterms, then the lowest midterm is dropped and the average of the two midterms with the higher grades is 35% of the course grade.

Final: Finals are graded on a scale from 0 to 10. The final is 40% of the course grade.

Write a computer program in a script file that determines the course grade for a student. The program first asks the user to enter the five quiz grades (in a vector), the three midterm grades (in a vector), and the grade of the final. Then the program calculates a numerical course grade (a number between 0 and 100). Finally, the program assigns a letter grade according to the following key: *A* for $\text{Grade} \geq 90$, *B* for $80 \leq \text{Grade} \leq 90$, *C* for $70 \leq \text{Grade} \leq 80$, *D* for $60 \leq \text{Grade} \leq 70$, and *E* for a grade lower than 60. Execute the program for the following cases:

- (a) Quiz grades: 7, 9, 4, 8, 7. Midterm grades: 93, 83, 87. Final grade: 89.
- (b) Quiz grades: 8, 6, 9, 6, 9. Midterm grades: 81, 75, 79. Final grade: 72.

34. The handicap differential (*HCD*) for a round of golf is calculated from the formula:

$$HCD = \frac{(\text{Score} - \text{Course Rating})}{\text{Course Slope}} \times 113$$

The course rating and the slope are measures of how difficult a particular course is. A golfers handicap is calculated from a certain number *N* of their best (lowest) handicap scores according to the following table.

# Rounds played	<i>N</i>	# Rounds played	<i>N</i>
5-6	1	15-16	6
7-8	2	17	7
9-10	3	18	8
11-12	4	19	9
13-14	5	20	10

For example, if 13 rounds have been played, only the best five handicaps are used. A handicap cannot be computed for fewer than five rounds. If more than 20 rounds have been played, only the 20 most recent results are used.

Once the lowest N handicap differentials have been identified, they are averaged and then rounded down to the nearest tenth. The result is the player's handicap. Write a program in a script file that calculates a persons handicap. The program asks the user to enter the golfers record in a three columns matrix where the first column is the course rating, the second is the course slope, and the third is the players score. Each row corresponds to one round. The program displays the person's handicap. Execute the program for players with the following records.

(a)

Rating	Slope	Score
71.6	122	85
72.8	118	87
69.7	103	83
70.3	115	81
70.9	116	79
72.3	117	91
71.6	122	89
70.3	115	83
72.8	118	92
70.9	109	80
73.1	132	94
68.2	115	78
74.2	135	103
71.9	121	84

(b)

Rating	Slope	Score
72.2	119	71
71.6	122	73
74.0	139	78
68.2	125	69
70.2	130	74
69.6	109	69
66.6	111	74
